Strategy Design (ML Fin Data - Project 1)

Hair Albeiro Parra Barrera

Libraries

0. Scraping the SP500

In order to test the logic within the strategy, I have fetched functions that retrieve a number of sample stocks by sector from the SP500. This is done automatically by fetch_sp500_sectors.R.

0.0.1 SP500 Economic Sectors

The following function fetches and extract the economic sectors from the SP500, taken from Wikipedia.

```
# fetch the sectors as a dataframe
sp500_sectors <- f_get_sp500_sectors()
head(sp500_sectors)</pre>
```

```
##

0.0.3 Retrieving top sectors and stocks

Pack everything into one function to retrieve all the data

```
# Retrieve top 10 stocks by weight for each sector in the top 5 sectors from the SP500 (by weight)
sector_list <- f_retrieve_top_sp500(top_n_sectors = 6, top_n_stocks = 20, only_tickers=TRUE)
sector_list</pre>
```

```

BACKTESTING LOGIC

Adding a numeric index

The data-fetching logic includes addition of a numerical index indicating to which month in the simulation the observations belong.

```
# count number of weeks in data from one of the dataframes
sample_xts <- sp500_stocks$Industrials$CSX
tail(sample_xts, 10)</pre>
```

```

BACKTESTING PROCEDURE

- 1. Assume we have N_{years} years of weekly data, giving a total of N_{months} many months. 2. We want to fix a window of $N_W = 12$ months at the time (i.e. a year of data).
- 2. The total number of runs is given by

$$N^{runs} = \left| \frac{N_{months} - N_W}{s} \right| + 1$$

, where s = 1 is the number of months to move at the time (because of monthly rebalance).

i.e., we can move N^{runs} times when predicting one month at the time, starting with having all the data until month 12.

That is, $\tau = 1, ..., 48$

```
# Set up backtesting simulation parameters
sample_xts <- sp500_stocks$Industrials$ADP</pre>
sectors <- names(sp500_stocks)</pre>
N_sector_best_stocks <- 3 # new strategy: 3x2 = 6
# Formula parameters
slide <- 1
N months <- length(names(split.xts(sample xts, f= "months")))
N_window <- 24 # number of months in size for each window
N_runs <- floor((N_months - N_window)/slide)</pre>
# display parameters
print(paste0("N_months: ", N_months))

SECTOR_PROCEDURE

τ and window logic

- 1. Sector G contains tickers $\{S_1, S_1, \ldots, S_{|G|}\}$, where |G| = number of stocks per sector (before selection).
- 2. For each ticker, want to calculate current window:

$$[t_1 = \text{week } W_{s \times \tau} \text{ , } t_{12} = \text{week } W_{s \times \tau+11}]$$

e.g. with s = 1 (slide one month at the time)

$$\begin{cases} \tau = 1 \implies [t_1 = W_1 \;,\; t_{12} = W_{12}] \\ \tau = 2 \implies [t_1 = W_2 \;,\; t_{12} = W_{13}] \\ \vdots \\ \tau = i \implies [t_1 = W_i \;,\; t_{12} = W_{i+11}] \\ \vdots \\ \tau = T \implies [t_1 = W_{T-12} \;,\; t_{12} = W_T] \end{cases}$$

EXTRACT_STATIC_FEATURES()

We had a set of features for some stock:

```
#get a sample stock xts data
sample_xts <- sp500_stocks$Industrials$ADP
tail(sample_xts, 5)</pre>
```

```

MODELLING_PROCEDURE

Recall that the **SECTOR_PROCEDURE** (G, τ) function takes the argument G, which is the **sector name**, and **tau**, which is the current run in the backtesting.

This procedure happens in a loop, for every sector G. Here, we fix one sector only, and a specific τ . The code does the following:

- 1. Retrieves the actual sector stock data (list of key-value pairs, keys are stock tickers, values are xts full data for that stock.)
- 2. Creates a variable to store the subset of data that goes into the current window.
- 3. The f_extract_window() function extracts the appropriate window of data corresponding to the τ , with the appropriate window size, for all sectors.
- 4. Extracts the dynamic features (ARIMA and GARCH) for that each stock in the sector.

```
# parameters
G <- names(sp500_stocks)[1] # sample sector
tau <- 10 # suppose we are in run 5 of the backtest

####### Inside SECTOR_PROCEDURE #######

# retrieve sector data
sector_data <- sp500_stocks[[G]]

# stocks for sector provided
sector_tickers <- names(sector_data)

# to store subset features for window
sector_stocks_window <- rep(NA, length(sector_tickers))
names(sector_stocks_window) <- sector_tickers</pre>
```

```
# extract static train-val for all stocks
list_xts_sector <- lapply(sector_data,</pre>
                          f_extract_window,
                          tau=tau, # current run
                          n months = N window# size of window
                          )
# compute dynamic features for all stocks
list_xts_sector <- lapply(list_xts_sector,</pre>
                          f_extract_dynamic_features,
                          arima_col = "realized_returns",
                          volat_col = "volat"
                          )

# save data in tests
save(list_xts_sector, file = here("tests","jair", "sample_data.rda"))
```

The result is the list_train_val_sector oject, which is a list of lists. - The first level are the stock tickers - The second level are train and val xts for each stock.

```
# Check num of rows (weeks) for window
nrow(list_xts_sector[[1]])
```

[1] 103

Feature Selection

Notes: - This will use **forward selection** to extract the features from a sample stock for the current sector. - The target_var argument specifies the target variable, in this case is called "realized_returns". - f_select_features() is found under functions/feature_engineering.R

```
target_var = "realized_returns", # future-lagged log-returns
volat_col = "volat", # we always want to keep the volatility col
garch_col = "vol_forecast", # GARCH column
nvmax = 50, # maximum number of subsets to examine
method="backward") # we always want to use forward selection
```

```
